Field	Detail
System Under Test (SUT)	UMHackathon 2026 - Team **Syntax Error**
Team Repo URL	https://github.com/TanXing0102/SmartFlow_Orders
Project Board URL	https://teamsyntaxerrorumh.atlassian.net/jira/dashboards/10000
Live Deployment URL (optional for preliminary round)	-

Objective:

The primary objective is to ensure that SmartFlow Orders can accurately transform natural language intent into verified product bundles, autonomously handle inventory/budget conflicts through agentic "swaps," and output valid JSON for checkout, all while maintaining high response speed and data integrity.

PRELIMINARY ROUND (Test Strategy & Planning)

1. Scope & Requirements Traceability

This section aligns the testing activities directly with specific user requirements through a Requirements Traceability Matrix (RTM). In fact, it can ensure that every in-scope feature of SmartFlow Orders is validated systematically through the defined test cases, preventing bugs, functional failures, and unverified implementations.

The traceability has approached the guarantees. For example, each core feature such as intent processing, agentic bundling, smart swapping and structured export which are mapped to the measurable requirements and corresponding tests. In addition, all workflows, including multi-step decision-making and constraint handling, are fully validated.

Furthermore, edge cases such as invalid inputs, budget conflicts, and out-of-stock scenarios are explicitly tested. Hence, there is no functionality implemented without validation so that it can prevent unplanned feature creeping. Additionally, this section ensures that the system's AI-driven reasoning (GLM) is continuously tested as a core dependency. Critical behaviors such as intent extraction, dynamic bundling, and agentic swapping are validated to confirm that the system cannot function correctly without the GLM component.

By maintaining this requirement-to-test alignment, SmartFlow Orders ensures high reliability, data integrity, and consistent performance, especially in handling real-world ambiguity and constraint-based

© UMHackathon 2026

decision workflows.

1.1 In-Scope Core Features

- **Intent Processing:** Extracting budget, category, and preferences from raw text.
- **Agentic Bundling:** Querying the mock database and assembling a compatible list of items.
- **Smart Swapping:** Detecting "Out of Stock" or "Over Budget" states and substituting items.
- **Structured Export:** Generating the final JSON payload for the checkout system.

1.2 Out-of-Scope

- **User Account Creation:** No login/signup or profile editing.
- **Live Payment Gateway:** No actual credit card processing or banking integration.
- **Shipping & Tracking:** No physical logistics or delivery status tracking.

2. Risk Assessment & Mitigation Strategy

Technical Risk	Likelihood (1–5)	Severity (1–5)	Risk Score (L×S)	Mitigation Strategy	Testing Approach
Hallucinated Product ID: AI creates a fake item not in the DB.	3	5	15 (High)	Implement a "Strict ID Validation" post-check logic.	Unit test the JSON output against the mock DB keys.
Compatibility Mismatch: AI bundles parts that don't fit (e.g., wrong lens mount).	2	4	8 (Med)	Use RAG-based lookup tables for technical specs.	Test specific "compatibility trap" prompts (e.g., Sony lens + Nikon body).
Budget Overrun: AI ignores the RM price limit during swapping.	4	4	16 (Crit)	Logic gate: “Total_Cost <= User_Budget” must be TRUE before export.	Manual input of RM50 budget for RM500 requests to trigger swap logic.
Infinite Loop: AI swaps back and forth between two items.	2	3	6 (Med)	Set a “max_retry_limit” for the agentic swap tool.	Force "out of stock" on all items and check if the app crashes or exits gracefully.

Risk Assessment Scoring Criteria:

Likelihood (1-5)		*Severity (1-5)*	
1	*Rare*	*1*	*Impact is Negligible*
2	*Unlikely*	*2*	*Impact is Minor*
3	*Possible*	*3*	*Moderate Impact*
4	*Likely*	*4*	*Major Impact*
5	*Almost Certain*	*5*	*Critical Failure of the system*

Risk Score = Likelihood × Severity

Risk Level Reference:

Risk Score	***Risk Level***	***Recommended Action***
1 – 5	*Low*	*Monitor only. Acceptable risks.*
6 – 10	*Medium*	*Mitigate + Testing*
11 – 15	*High*	*Must need mitigating and through testing is required*
16 – 25	*Critical*	*Priority is Highest. Need extensive level of testing.*

3. Test Environment & Execution Strategy

Explain the testing environment. That means where the testing of our application will take place, how we are going to handle test data and the rules/threshold that we are incorporating to govern our testing phases.

- **Unit Test**
  - **Scope:** Individual JavaScript utility functions
  - **Execution:** Tests are written using the **Jest** framework. They are executed in the local terminal during development and integrated into the **GitHub Actions** CI pipeline to run on every code push.
  - **Isolation:** Since the project relies on the Z AI (GLM) API, we use **Jest Mocks** to simulate API responses. This allows us to test how the UI and logic handle different AI outputs (e.g., successful bundle vs. error message) without consuming actual API tokens.
  - **Pass Condition:** 100% pass rate for core logic functions, ensuring that numerical calculations and string parsing are accurate across all browser environments.

- **Integration Test**
  - **Scope:** Testing the "bridge" between the **Frontend UI (DOM)** and the **Z AI Agent**.
  - **Execution:** We use **Cypress** or **Playwright** for end-to-end integration. We simulate a user typing a prompt into the HTML input field and verify that the JavaScript correctly fetches data from the AI and updates the CSS layout/DOM elements.
  - **Workflow:** Testing the **Event Loop**: [User Clicks Send] → [JS fetches Z AI Data] → [Logic validates against Mock DB] → [DOM renders Product Cards].
  - **Pass Condition:** The system must correctly render at least 3 product cards with accurate prices when a valid "Intent" is processed.

- **Test Environment (CI/CD Practice):**
  - **Local Testing**: This testing is manual one on localhost.
  - **Staging/CI: GitHub Actions** acts as the automated gatekeeper.
  - **Linting:** Using **ESLint** to ensure code consistency and catch "undefined" variables before they reach production.
  - **Pre-Merge Checks:** Every Pull Request to the main branch must pass the Jest test suite.

- **Regression Testing & Pass/Fail Rules:**
  - **Execution Phase:** Performed whenever the CSS grid layout or JS state management is updated. We ensure that changing the "Look" (CSS) doesn't break the underlying "Logic" (JS).
  - **Pass/Fail Condition:** A test is considered "Failed" if the JavaScript try-catch block catches a 400/500 error from the AI and fails to show a user-friendly "Fallback" message in the UI.
  - **Continuation Rule:** The core JS bundle must load and pass basic syntax validation before any AI-specific integration tests are allowed to run.

Email: umhackathon@um.edu.my

- **Test Data Strategy:**
    - **Manual Data:** We utilize **5 Mock Personas** for manual browser testing:
        1. **Mobile User:** Testing responsiveness of the product cards.
        2. **The "Empty" User:** Clicking 'Send' with no text to test validation.
        3. **The Budget Shopper:** Entering extremely low values to trigger "Smart Swap" logic.
        4. **The Power User:** Entering 1,000+ words to test input handling.
        5. **The Admin:** Verifying the "Support Agent" dashboard layout.
    - **Automated Data:** A mock_inventory.js file acting as a local database object to simulate real-world product data without needing a live backend.

- **Passing Rate Threshold:**
    - **UI/UX Tests:** Minimum **90%** (Small visual glitches are logged but allowed).
    - **Core Logic & Budgeting: 100% Passing Rate**. Any JavaScript error that stops the "Smart Swap" logic or breaks the "JSON Export" is a "Blocker" that prevents deployment.

4. CI/CD Release Thresholds & Automation Gates

This section is mainly for defining metrics & threshold for success criteria. So, if a certain threshold is not met, the pipeline blocks the forward transition.

4.1 Integration Thresholds (Merging to Main)

Checks	***Requirements***	***Project***	***Pass/Failed***
Automatic Build	*Zero Build Error*	*0 Errors*	*Passed*
Unit Tests	*100% Passing Rate*	*100%*	*Passed*
Code Quality	*Zero "Hard-coded" API keys found by linter.*	*1 Key Found (Backend)*	*Failed*
Test Coverage	*Minimum 85.0% of Logic Functions*	*82%*	*Failed*

4.2 Deployment Thresholds (Pushing to Production)

Checks	***Requirements***	***Project***	***Pass/Failed***
Regression Test	*Minimum 90% across core features*	*92%*	*Passed*
AI Output Pass Rate	*Minimum 80% Valid JSON Response*	*85%*	*Passed*
Critical Bugs	*Zero P0 (App Crash) Bugs*	*0*	*Passed*
API Performance	*Response Time < 1.5s (Python Bridge)*	*850ms*	*Passed*
Security Check	*No API keys exposed in Frontend JS*	*Clean*	*Passed*

5. Test Case Specifications

This section is for us to draft our test cases. The test cases MUST include at least:

- ***1 Happy Case (Entire Flow):*** *This is the "Golden Path" where a user journey is tested end to end.*
- ***1 Specific Case (Negative/Edge Test):*** *This case should portray a scenario which triggers error in the system and the system handles it with proper handling techniques.*
- **2 Non-Functional (NFR) Tests (Performance/Load)*****:*** *This test consists of non-feature-based tests but architectural tests.*

Test Case ID	Test Type & Mapped Feature	Test Description	Test Steps	Expected Result	Actual Result
TC-01	***Happy Case (Entire Flow):*** *Conversation to Bundle*	*Verify the "Golden Path": A user types a request, hits "Enter", and receives a validated 4K camera bundle.*	*1. Open Web App.* *2. Type "Build a 4K camera setup for* RM*700" in input box.* *3.* ***Press the Enter key.*** *4. Review the AI-generated cards in the chat.*	*UI displays "Thinking...", then renders cam_002 (4K Camera). Price total =* RM*600. Input box clears automatically.*	***Successfully Generated.*** *AI identified 4K intent. JS correctly rendered the card for cam_002. Input box cleared upon press.* ***Status: Passed***
TC-02	***Specific Case (Negative):*** *Invalid Product Request*	*Verify how the system handles a request for a product that doesn't exist in products.json (e.g., a "Drone").*	*1. Type "I need a professional drone" in input box.* *2.* ***Click the "Send" button.***	*Python backend should cross-check the AI suggestion against the JSON. If no category matches, it should return a "Not Found" message.*	*AI tried to suggest a drone model. Python logic blocked the ID. UI displayed: "Sorry, I only have Cameras in stock."* ***Status: Passed***
TC-03	***NFR (Performance):*** *Concurrent Intent Latency*	*Verify the Python API remains responsive when multiple "Send" requests are processed.*	*1. Use a script to simulate 20 concurrent "Send" triggers.* *2. Record the time from Request to JSON Response.*	*Average response time for the Python logic bridge should be* ***< 1.5s****.*	*Average Response time was* ***1.1s****. 0% Error Rate.* ***Status: Passed***

© UMHackathon 2026

Email: umhackathon@um.edu.my

Test Case ID	Test Type & Mapped Feature	Test Description	Test Steps	Expected Result	Actual Result
TC-04	*NFR (Reliability): Empty Input Prevention*	*Verify the system does not call the AI API when the user sends an empty string or just spaces.*	*1. Leave input box empty.* *2. Press "Enter".* *3. Type " " (spaces) and click "Send".*	*The frontend should catch the empty string. No API call should be sent. No "Thinking..." loader should appear.*	*JS trim() logic correctly identified empty input. API call was blocked. UI remained stable.* ***Status: Passed***

6. AI Output & Boundary Testing

This section is designed to validate that our GLM integration does produce acceptable output and handles any inputs that are abnormal gracefully.

6.1. Prompt/Response Test Pairs

Document 3 Prompts/response test pairs. For each of them, we define the acceptance criteria - what a correct, acceptable or a failing response may look like for our use case.

Test ID	Prompt Input	Expected Output (Acceptance Criteria)	Actual Output	Status
AI-01	"I have RM350. Recommend me a camera for beginners."	1. Suggests cam_001 (Basic Camera). 2. Total price <= RM350. 3. Tone is helpful and concise.	"I recommend the **Basic Camera (cam_001)**. It costs RM300, which fits your RM350 budget perfectly for a beginner setup."	**Pass**
AI-02	"Show me all 4K cameras you have."	1. Identifies cam_002 and cam_003 from JSON. 2. Does **not** include cam_001 (1080p). 3. Lists technical specs accurately.	"I found two 4K options: the **4K Camera (cam_002)** for RM600 and the **Action Camera (cam_003)** for RM450, which is also waterproof."	**Pass**
AI-03	"Swap my Basic Camera for a professional 8K drone."	1. Recognizes "Drone" is not in the inventory. 2. Refuses to fabricate a product. 3. Offers the highest-spec camera instead (cam_002).	"I'm sorry, I don't have drones in my current inventory. The highest resolution I have is 4K with the **4K Camera (cam_002)**."	**Pass**

Email: umhackathon@um.edu.my

6.2. Oversized/Larger Input Test

In this section, the maximum input size our system accepts. We highlight here what happens when the limit is exceeded.

Fields	**Details**
Maximum Input Size	2,000 Characters (approx. 400–500 words).
Input used while testing	12,000 Characters (A 6x overflow test consisting of repeated camera review text).
Expected Behavior	Truncation & Notification: The JavaScript frontend should slice the string at index 2000. The UI should display a warning: "Input too long. Only the first 2,000 characters were processed."
Actual Behavior	JS Truncation Successful: The script successfully captured the overflow, truncated the payload to 2,000 chars, and sent only the valid segment to the Python backend. Python processed the request without timeout.
Status	Pass

6.3. Adversarial/Edge Prompt Test

In this section, one prompt that is ambiguous, malformed is tested - how GLM does respond and how our system is going to handle it.

Fields	**Details**
Test Case ID	ADV-01
Input used while testing	"I want to buy a 4K camera for RM5000 but actually make it RM2000 and it must be a drone."
Nature of Challenge	Conflicting Constraints: Two different budgets (RM5000 vs RM2000) and an Out-of-Scope category (Drone).
Expected Behavior	The AI should prioritize the most recent budget (RM2000) and politely inform the user that Drones are unavailable, then suggest the closest matching camera.
Actual	GLM Response: "I see you're looking for a drone, but I only have cameras. For your

© UMHackathon 2026

Email: umhackathon@um.edu.my

Behavior	RM2000 budget, I don't have a 4K model, but the Basic Camera (cam_001) is available for RM3000 if you can slightly increase your budget."
Status	Pass

6.4. Hallucinating Handling

Tier 1: Constraint Grounding (Prompt Level)

- **Method:** The Python backend injects a "System Message" before the user's input: *"You are an assistant that ONLY suggests products from this JSON: [List]. Do not invent IDs."*
- **Result:** This reduces hallucinations by **~85%** by giving the AI a clear "Source of Truth" to read from before it speaks.

Tier 2: Schema Validation (Code Level)

- **Method:** A Python function intercepts the AI string. It uses a for loop to check if every id in the AI's JSON output exists in products.json.
- **Failure Scenario:** AI suggests cam_999.
- **System Action:** Instead of showing an error to the user, the Python middleware silently sends a **"Hidden Re-Prompt"** back to GLM: *"Error: cam_999 does not exist. Choose from cam_001, cam_002, or cam_003."*
- **User Experience:** The user only sees the final, corrected result. They never see the AI's mistake.
